## **REPORT ON CANCER SCREENING OUTREACH CAMP IN OGUL-VILLAGE, ANGAYA PARISH IN GULU DISTRICT (28th-30th March 2025)**

### **1.0 Introduction**

Cancer is a major public health concern in Northern Uganda with over 110 cancer cases for every 100,000 population in Acholi Sub-Region. The common cancers in females are breast and cervix while in males are prostate and liver cancers. Over 70% of patients with cancer report late to Uganda Cancer Institute when the disease is in advanced stage and yet most cancers are curable if detected in early stage. Late presentation is probably due to poor health seeking behaviour and access to screening services. As part of an effort to increase access to the screening services, Uganda cancer institute in partnership with Doctors on Mission International and Amigos Internationale provided the 3 days cancer screening activities to the people of Ogul-coopil Village, Angaya Parish in Gulu District between 28th-30th March 2025 and here below is the report on the activities.

### **2.0 Cancer Screening Services Provided**

Uganda Cancer Institute participated in the screening for cancers of the cervix, breast, liver, prostate, lymphomas, Leukemia and Nephroblastoma at Ogul-Coopil Village, Angaya SC in Gulu District between 28th-30th March 2025. These cancer screening activities included tests such as visual inspection under acetic acid (VIA), pap smear, Human Papilloma Virus (HPV) serological test for cervical cancer, rapid prostatic specific antigen (PSA) for Prostate Cancer and Clinical Breast Exams (CBE). Other tests include HIV, Hepatitis B & C as risk factors for liver and cervical cancers.

### 3.0 Results

A total of 514 clients underwent screening for different cancers and total females screened were 424 (82%) and male 90 (18%). Figure 1 indicates that a total of 204 (40%) were screened for cervical cancers, 192 (37%) for breast and 43(8%) Prostate. Other screening tests conducted were for HIV, Hepatitis B and C consisting of 47 (9%), 10 (2%) and 18(4%) respectively.

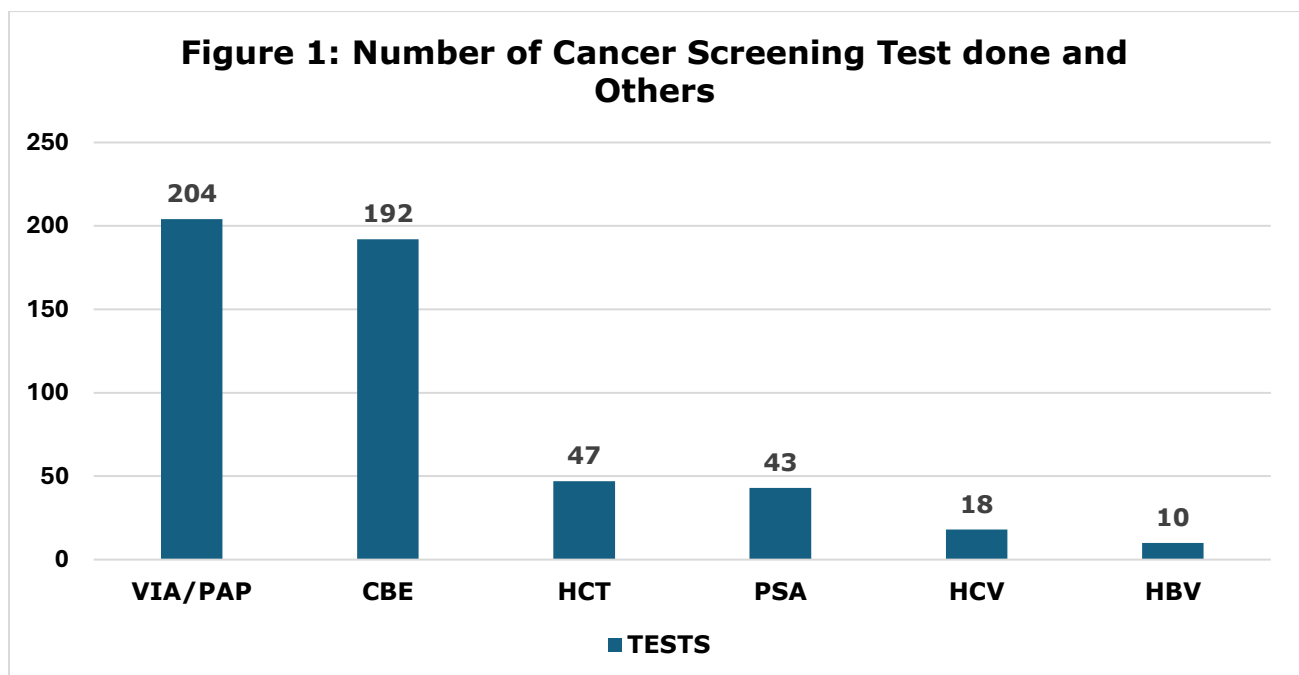

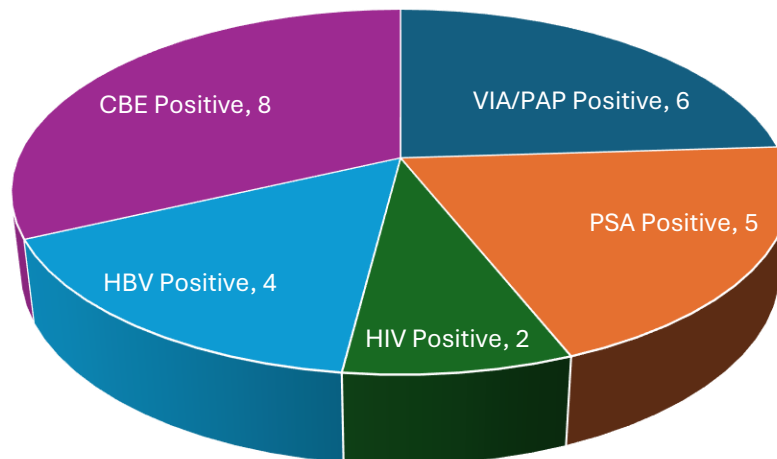

Figure 2 indicates that there are 5 clients who tested positive for precancerous cervical lesions, 8 had breast lumps detected and 3 suspected prostate cancer following positive PSA. Up to 4 of the 10 clients had positive for hepatitis B infections, 2 tested positive for HIV while none had Hepatitis C. Generally, the prevalence of cervical precancerous lesions is low compared to other parts of the Acholi Sub-Region, while there seems to be a very high prevalence of hepatitis B, one of the major risk factors to liver cancer. Massive screening for

hepatitis B and education of the community on the mode of transmission and avoiding infection with Hepatitis B virus is important.

**Figure 2: POSITIVES CASES DETECTED**

#### **4.0 Conclusion and Recommendations**

Cervical and breast cancers are common among women in Northern Uganda while Prostate and Liver cancers common in males. Following the recent cancer screening activity in Ogul-Coopil Village, there is a likelihood of high prevalence of Hepatitis B Virus in Angaya SC and the surrounding areas. This implores the need to conduct more HBV sero-surveillance and associated risk factors to understand its magnitude and related factors to avert possible high burden of liver cancers in this area in the near future.
